Outline

Relationship between file descriptors and open files

- Multiple file descriptors can refer to same open file
- 3 kernel data structures describe relationship:
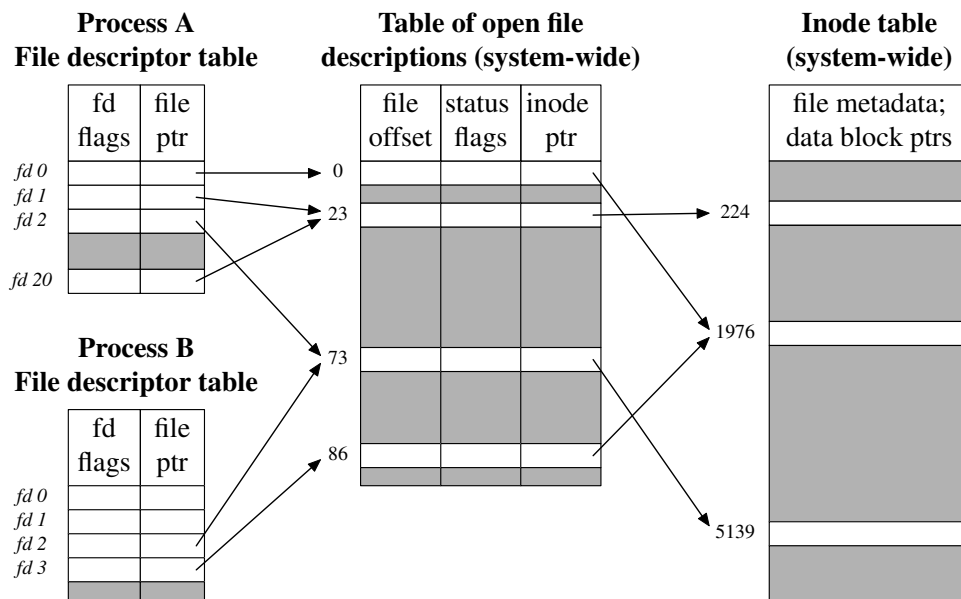

File descriptor table

Per-process table with one entry for each FD opened by process:

- Flags controlling operation of FD (close-on-exec flag)
- Reference to open file description
- *struct fdtable* in `include/linux/fdtable.h`

Table of open file descriptions (open file table)

System-wide table, one entry for each open file on system:

- File offset
- File access mode (R / W / R-W, from *open()*)
- File status flags (from *open()*)
- Reference to inode object for file
- *struct file* in `include/linux/fs.h`

Following terms are commonly treated as synonyms:

- **open file description (OFD)** (POSIX)
- **open file table entry** or **open file handle**
  - ⚠ Ambiguous terms; POSIX terminology is preferable

# (In-memory) inode table

System-wide table drawn from file inode information in filesystem:

- File type (regular file, FIFO, socket, . . .)
- File permissions
- Other file properties (size, timestamps, . . .)
- *struct inode* in `include/linux/fs.h`

Duplicated file descriptors (intraprocess)

A process may have multiple FDs referring to same OFD

- Achieved using *dup()* or *dup2()*

Duplicated file descriptors (between processes)

Two processes may have FDs referring to same OFD
- Can occur as a result of *fork()*

Process A File descriptor table		Table of open file descriptions (system-wide)			Inode table (system-wide)
fd flags	file ptr	file offset	status flags	inode ptr	file metadata; data block ptrs

Distinct open file table entries referring to same file

Two processes may have FDs referring to distinct OFDs that refer to same inode
- Two processes independently *open()*ed same file

Process A File descriptor table		Table of open file descriptions (system-wide)			Inode table (system-wide)
fd flags	file ptr	file offset	status flags	inode ptr	file metadata; data block ptrs

Why does this matter?

- Two different FDs referring to same OFD share file offset
  - (File offset == location for next *read()*/*write()*)
  - Changes (*read()*, *write()*, *lseek()*) via one FD visible via other FD
  - Applies to both intraprocess & interprocess sharing of OFD
- Similar scope rules for status flags (`O_APPEND`, `O_SYNC`, ...)
  - Changes via one FD are visible via other FD
    - (`fcntl(F_SETFL)` and `fcntl(F_GETFL)`)
- Conversely, changes to FD flags (held in FD table) are private to each process and FD
- *kcmp(2)* `KCMP_FILE` operation can be used to test if two FDs refer to same OFD
  - Linux-specific

[TLPI §5.4]

Outline

A problem

```
./myprog > output.log 2>&1
```

- What does the shell syntax, 2>&1, do?

- How does the shell do it?

- Open file twice, once on FD 1, and once on FD 2?
    - FDs would have separate OFDs with distinct file offsets $\Rightarrow$ standard output and error would overwrite
    - File may not even be *open()*-able:
        - e.g., ./myprog 2>&1 | less

- Need a way to create duplicate FD that refers to same OFD

[TLPI §5.5]

Duplicating file descriptors

```
#include <unistd.h>
int dup(int origfd);
```

- Arguments:
    - *origfd*: an existing file descriptor
- Returns new file descriptor that refers to same OFD
- **New file descriptor is guaranteed to be lowest available**

Duplicating file descriptors

- FDs 0, 1, and 2 are normally always open, so shell can achieve 2>&1 redirection by:

```
close(STDERR_FILENO);          /* Frees FD 2 */
newfd = dup(STDOUT_FILENO);  /* Reuses FD 2 */
```

- But what if FD 0 had been closed beforehand?
    - *dup()* would reuse FD 0...
   - We need a better API

Duplicating file descriptors

```
#include <unistd.h>
int dup2(int origfd, int newfd);
```

- Like *dup()*, but uses *newfd* for the duplicate FD
    - **Silently** closes *newfd* if it was open
    - Close + reuse of *newfd* is done as an atomic step
        - Important: otherwise, *newfd* might be re-used in between
    - Does nothing if *newfd == origfd*
    - Returns new file descriptor (i.e., *newfd*) on success
- dup2(STDOUT_FILENO, STDERR_FILENO);
- See *dup2(2)* manual page for more details

[TLPI §5.5]

Understanding *dup2(origfd, newfd)*
- If *newfd* was an open FD, OFD-b will be released if *newfd* was the last FD that referred to it

- After *dup2()*, *origfd* and *newfd* share file offset and file status flags

Outline

File status flags

- Control semantics of I/O on a file
    - (`O_APPEND`, `O_NONBLOCK`, `O_SYNC`, . . .)
- Associated with open file description
- Set when file is opened
- Can be retrieved and modified using *fcntl()*

[TLPI §5.3]

fcntl() : file control operations

```
#include <fcntl.h>
int fcntl(int fd, int cmd /* , arg */ );
```

Performs control operations on an open file

- Arguments:
    - *fd* : file descriptor
    - *cmd* : the desired operation
    - *arg* : optional, type depends on *cmd*
- Return on success depends on *cmd*; −1 returned on error
- Many types of operation
    - file locking, signal-driven I/O, file descriptor flags . . .

Retrieving file status flags and access mode

- Retrieving flags (both access mode and status flags)

```
int flags = fcntl(fd, F_GETFL);
```

- Check access mode

```
int amode = flags & O_ACCMODE;
if (amode == O_RDONLY || amode == O_RDWR)
    printf("File is readable\n");
```

- ⚠ 'read' and 'write' are not separate bits!

```
if (flags & O_RDONLY)        /* Wrong!! */
    printf("File is readable\n");
```

- Access mode is a 2-bit field that is an enumeration:
    - $00 == $ O_RDONLY; $01 == $ O_WRONLY; $10 == $ O_RDWR
    - (O_ACCMODE $== 11_2$)
- Access mode can't be changed after file is opened

Retrieving and modifying file status flags

- Retrieving file status flags

```
int flags = fcntl(fd, F_GETFL);
if (flags & O_NONBLOCK)
    printf("Nonblocking I/O is in effect\n");
```

- Setting a file status flag

```
int flags = fcntl(fd, F_GETFL);      /* Retrieve flags */
flags |= O_APPEND;                    /* Set "append" bit */
fcntl(fd, F_SETFL, flags);            /* Modify flags */
```

  - ⚠ Not thread-safe...
    - (But in many cases, flags can be set when FD is created, e.g., by *open()*)

- Clearing a file status flag

```
int flags = fcntl(fd, F_GETFL);      /* Retrieve flags */
flags &= ~O_APPEND;                   /* Clear "append" bit */
fcntl(fd, F_SETFL, flags);            /* Modify flags */
```

Exercise

1. Show that duplicate file descriptors share file offset and file status flags by writing a program ([template: `fileio/ex.fd_sharing.c`]) that:
   - Implements the function *printFileDescriptionInfo()*, which, given a file descriptor as an argument, displays the file offset and the state of the `O_APPEND` file status flag associated with that file descriptor.
   - Opens an existing file (supplied as *argv[1]*) and duplicates (*dup()*) the resulting file descriptor, to create a second file descriptor.
   - Uses the *printFileDescriptionInfo()* function to display the file offset and the state of the `O_APPEND` file status flag via the first file descriptor.
     - Initially the file offset will be zero, and the `O_APPEND` flag will not be set
   - Changes the file offset (*lseek()*, slide 5-5) and enables (turns on) the `O_APPEND` file status flag (*fcntl()*, slide 5-41) via the second file descriptor.
   - Uses the *printFileDescriptionInfo()* function to display the file offset and the state of the `O_APPEND` file status flag via the first file descriptor.

   Hints:
   - Remember to update the `Makefile`!
   - `while inotifywait -q . ; do echo -e '\n\n'; make; done`
